Two proofs of the Riemann Hypothesis

Dr. Klaus Braun
79106 Freiburg i. Br.
June 30, 2013

Abstract

This note gives a summary of corresponding papers [KBr1], [KBr2], [KBr3] in

www.riemann-hypothesis.de.

The Riemann Hypothesis states that the non-trivial zeros of the Zeta function all have real part one-half. The Hilbert-Polya conjecture states that the imaginary parts of the zeros of the Zeta function corresponds to eigenvalues of an unbounded self-adjoint operator. All attempts failed so far to represent the Riemann duality equation in the critical stripe as convergent (!) Mellin transforms of an underlying self-adjoint integral equation relation. The constant, not vanishing Fourier terms of the Theta functions are the root cause of only formally self-adjoint invariant operator definitions with corresponding (Mellin) transform of the Riemann duality equation ((HEd) 10.3). The idea of our two proofs is built on appropriately defined (weak) self-adjoint integral equations in a distribution sense and its related Mellin transforms. The distributional approach is the prize to be paid to build convergent (!) Mellin transform integrals ((HEd) chapter 10). The Mellin transform can be seen as a Fourier transformation on the multiplicative group of positive real numbers [AZe]. It corresponds to an isometry between Hilbert spaces of functions.

Let \( H = L^2_s(\Gamma) \) with \( \Gamma := S^1(R^3) \), i.e. \( \Gamma \) is the boundary of the unit sphere. Let \( \mu(s) \) being a \( 2\pi - \) periodic function and \( \int \) denotes the integral from \( 0 \) to \( 2\pi \) in the Cauchy-sense. Then for \( u \in H \Rightarrow L^2_s(\Gamma) \) with \( \Gamma := S^1(R^3) \) and for real \( \beta \) the Fourier coefficients
\[
\hat{u}_{\beta} := \frac{1}{2\pi} \int u(x)e^{-\beta x} \, dx
\]

enable the definitions of the norms (e.g. [ILu] 11.1.5, [KBr0])

\[
\|u\| \overset{L^2}{=} \sum_{\beta} \|\hat{u}_{\beta}\|^2
\]

We give two distributional representations \( \zeta_i(s), i = -1,0 \) of the Zeta function ([BPe], [AZe]) as Mellin transforms of proper Hilbert space (distributional) functions \( \alpha_i(s) \in H_i \). They are built on the Hilbert transforms
\[
f_{\alpha}(x) = 4\pi \int_0 f(\xi)\sin(2\pi x\xi)d\xi
\]

of the Gauss-Weierstrass function \( f(x) = e^{-x^2} \) and the fractional part function
\[
\rho(x) = x - [x] = \frac{1}{2} - \sum_{n=1}^{\infty} \frac{\sin(2\pi n x)}{2\pi n}
\]

The corresponding convolution integral representations in the Hilbert spaces \( H_i \) enable the application of spectral analysis arguments ([GPo]) to prove that all zeros of \( \zeta_i(s) \) lie on the critical line, which is characterized by the identity \( s = 1 - s \).

The distributional “functions” \( \zeta_i(s) \) are identical to the Zeta function \( \zeta(s) \) in a weak sense with respect to the inner products of the Hilbert spaces of functions \( H_i \). This proves the RH in a weak sense. By standard (functional analysis) density arguments then it follows that the RH is also valid in the strong sense.
Notations

Let $H = L_2^4(\Gamma)$ with $\Gamma := S^1(R^2)$, i.e. $\Gamma$ is the boundary of the unit sphere. Let $u(s)$ being a $2\pi$-periodic function and $\int$ denotes the integral from $0$ to $2\pi$ in the Cauchy-sense. Then for $u \in H := L^4_2(\Gamma)$ with $\Gamma := S^1(R^3)$ and for real $\beta$ the Fourier coefficients

$$ u_{\nu} := \frac{1}{2\pi} \int u(x) e^{-i\nu x} \, dx $$

enable the definitions of the norms (see e.g. [ILi] Remark 11.1.5, [KBr0], see also [BHa])

$$ \|u\|_{\beta}^2 := \sum_{-\infty}^{\infty} |\nu|^2 \|u_{\nu}\|^2. $$

There is a natural representation of the Fourier decomposition

$$ u(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos(nx) + \sum_{n=1}^{\infty} b_n \sin(nx) := \sum_{n=1}^{\infty} u_{\nu} e^{i\nu x} \in L_2 $$

as Laurent series description in terms of a complex variable, defined on a circle $z = e^{ix}$:

$$ \tilde{u}(z) := u(x) = \sum_{-\infty}^{\infty} u_{\nu} z^\nu \in H := L_2^4(\Gamma) $$

with

$$ u_{0} := \frac{a_0}{2}, \quad u_{\nu} := \frac{1}{2}(a_{\nu} - i b_{\nu}), \quad c_{\nu} := \frac{1}{2}(a_{\nu} + i b_{\nu}), \quad \nu > 0. $$

Then $H$ is the space of $L_2$ - periodic function in $R$.

Remark (*): From [DGa] pp.63 and [SGr] 1.441, we recall

$$ \frac{1}{2\pi} \int_{0}^{2\pi} \sin n\vartheta \cot \frac{\varphi - \vartheta}{2} d\vartheta = \begin{cases} \frac{-\cos(n\varphi)}{\sin(n\varphi)} & n \neq 0,1,2,3,... \\ 0 & n = 0 \end{cases} $$

resp.

$$ \frac{1}{2\pi} \int_{0}^{2\pi} e^{inx} \cot \frac{\varphi - \vartheta}{2} d\vartheta = \begin{cases} e^{i\text{sign} n} \frac{1}{2\pi} \int_{0}^{2\pi} \cos nx \, dx & n = 1,2,3,... \\ 0 & n = 0 \end{cases} $$

From [ILi] (1.2.34) we recall the following identity with a hypersingular integral equation of kernel of Hilbert type

$$ -n(a_n \cos nx_0 + b_n \sin nx_0) = \frac{1}{4\pi} \int_{0}^{2\pi} a_n \cos nx + b_n \sin nx \frac{dx}{\sin^2 \frac{x-x_0}{2}}, $$
This identity is related to the following integral operators ([IL] (1.2.31)-(1.2.33), [Il1])

(A) \[(Au)(x) := \int \log 2\sin \frac{x-y}{2}u(y)dy = \int k(x-y)u(y)dy \quad \text{and} \quad D(A) = H = L^1(\Gamma)\]

(H) \[(Hu)(x) := \left[u\right](x) := \frac{1}{2} \cot \frac{x-y}{2}u(y)dy = -\lim_{\epsilon \to 0} \frac{1}{2} \int [u(x+y) - u(x-y)]\cot \frac{y}{2}dy .\]

For a relationship between conjugate functions on the open unit disk and the Hilbert transform (H) above we recall from [DGa] Chapter II, §1:

**Theorem 1.1.** Let \(f(z) = u(z) + iv(z)\) \((u, v \text{ real})\) be regular in the open unit disk \(|z| < 1\) and continuous on the closed unit disk \(|z| \leq 1\). Then for \(v(e^{i\varphi})\) the following integral representation of \(u(e^{i\varphi})\) is valid (Cauchy integral):

\[v(e^{i\varphi}) = v(0) + \frac{1}{2\pi} \int e^{i\varphi}v(e^{i\varphi})\cot \frac{\varphi - \varphi_0}{2}d\varphi .\]

The following properties for the operators (A) and (B) are valid (e.g. [DGa] Chapter II, §1, [EST] chapter III, [NMu] §28, [BPe] 9.3):

**Lemma:**

i) The operator \(H\) is skew symmetric in the space \(L^2(0,2\pi)\) and maps the space \(H := L^2(0,2\pi) - \mathcal{R}\) isometric onto itself, and it holds

\[\|Hu\| = \|u\| \quad \text{and} \quad H^2 = -I , \quad (Hu,v) = -(u,Hv) \quad , \quad \left[u^T\right](x) = \left[u\right]^T(x)\]

\[(Hu)_v = -i\text{sign}(v)u_v \quad , \quad (Hu)(x) = \sum_{n=1}^{\infty} \left[u_x, e^{-ijn} - u_x, e^{ijn}\right] \in L^2 \quad \text{for} \quad u \in L^2\]

ii) The operator \(A\) is symmetric in its domain \(D(A)\) and the Fourier coefficients of the convolutions of both operators are

\[(Au)_v = k_vu_v = \frac{1}{2\pi}u_v \quad , \quad D(A) \subseteq H_\lambda = H_{-1/2}(\Gamma) .\]

**Remark:** As a consequence there are several relationships in the context of Euler’s formula (see ([ET] 2.1), [BPe]): Let \(\{x\}\) denote the largest integer not exceeding the real number \(x\) and let \(\rho(x) := \{x\} := x - [x]\) be the fractional part (sawtooth) function of \(x\).

i) \[\rho(x) = \{x\} = x - [x] = \frac{1}{2} - \sum_{n=1}^{\infty} \frac{\sin 2\pi nx}{2\pi n} \]

ii) \[-i\pi \text{sign}(x) = -2i \int_0^{\pi} \sin(tx)dt = 2i \int_0^{\pi} \sinh(tx)dt = \left[P_y(x)\frac{1}{x}\right] .\]

iii) \[\sum_{n=1}^{\infty} \frac{\sin nx}{n} = \frac{\pi - x}{2} \quad , \quad \sum_{n=1}^{\infty} \frac{\cos nx}{n} = \frac{1}{2} \log \frac{1}{2(1 - \cos x)} , \quad 0 < x < 2\pi .\]
**Remark:** The Hilbert spaces $H_{-1/2}, H_{-1}$ are characterized by
\[ H_{-1/2} = \{ \| \psi \|_{1/2}^2 = (A \psi, \psi)_0 < \infty \} , \quad H_{-1} = \{ \| \psi \|_1^2 = (A \psi, A \psi)_0 < \infty \}. \]

In [AZy], 5.28, 7.2, 13.11 the concept of “logarithmic”, $\alpha$ – capacity” of sets and convergence of Fourier series to functions with
\[ \sum_i n[a_i^2 + b_i^2] < \infty \]
is given. In this context we also refer to [BRi] and the still unanswered question in it. In ([AZy]) the following two examples are provided (see also [HEd] 9.7):
\begin{enumerate}
  \item \[ \lambda(x) = \sum_i \frac{\cos 2\pi vx}{v} = - \log 2 \sin(v\pi) \quad \text{whereby} \quad \sum_i \frac{\cos vx}{v} \leq \log \left( \frac{1}{x} \right) + C , \]
  \item \[ \lambda(x) = \sum_i \frac{\cos vx}{v} \equiv c_\alpha |v|^{-\alpha} , \quad (x \to 0, 0 < \alpha < 1) . \]
\end{enumerate}

In [CBe] 8, Entry17(iv) its relationship to Ramanujan’s divergent series technique is mentioned: “Ramanujan informs us to note that
\[ \sum_i \sin(2\pi vx) = \frac{1}{2} \cot(v\pi) , \]
which also is devoid of meaning” .... “may be formally established by differentiating the well known equality”
\[ \sum_i \frac{\cos 2\pi vx}{v} = - \log 2 \sin(v\pi) . \]

There is also a related representation of the Dirac function in the form
\[ \delta(x) = \frac{1}{2\pi} \int e^{ix\xi} d\xi = \frac{1}{\pi} \cos(\xi x) d\xi \in H_{-n/2} \subset H_{-1} \quad \text{for } n = 1. \]

We further note that in harmonic analysis the energy of the harmonic continuation $h = E(\phi)$ to the boundary is given by
\[ \| h \|^2 = \frac{2}{\pi} \sum_i v(a_i^2 + b_i^2) = \frac{1}{2} \int \| d\phi(z) \|^2 dx dy = \frac{1}{4\pi} \int \int \frac{1}{|v - \phi(z)|} d\mu(z) d\phi(z) < \infty . \]

Relationships to the Gamma function and the Euler constant are given e.g. by ([CBe] 8, entry 17(iv), [NNi]: Gammasfunktion §78, §88; Theorie des Integrallogarithmus V, §33):
\begin{enumerate}
  \item \[ \log \sin \pi x = \log \frac{\pi}{\Gamma^2(x)} + \frac{2}{\pi} \sum_i (\gamma + \log(2\pi x)) \frac{\sin(2\pi k x)}{k} \quad \text{for } 0 < x < 1 \]
  \item \[ \gamma = \frac{1}{2} + \sum \frac{\cos(2\pi x)}{t} . \]
\end{enumerate}
The Gauss-Weierstrass function and the fractional part function

The Theta function \( \theta \) is given by

\[
\theta(x) := \sum_{n} f(nx) := 1 + \psi(x^2) = \frac{1}{x} \theta\left(\frac{1}{x}\right),
\]

whereby \( f \) denotes the Gauss-Weierstrass density function

\[
f(x) := e^{-x^2}.
\]

**Lemma:** We note the identity \((\text{[NNi]} \, \S 88)\) \((a > 0)\)

i) \[
f(x) = \frac{e^{-x^2}}{2 \pi} \int_{-\infty}^{\infty} \Gamma\left(\frac{1}{2}\right)x^{-s}ds
\]

ii) \[
\Omega(s) := (s - 1) \int_{0}^{\infty} x^s (xf'(x))d\log x = (s - 1)\Gamma(1 + \frac{s}{2})\pi^{-s/2} = (s - 1) \int_{0}^{\infty} x^s (xf'(x)) \frac{dx}{x}
\]

iii) The Hilbert transform of the Gauss-Weierstrass function is given by

\[
[H(f)](x) = 4\pi \int_{0}^{\infty} f(\xi) \sin(2\pi\xi x)d\xi
\]

iv) It holds the identity \((\text{[CFo], appendix})\):

\[
[H(f)](s) = \frac{2\pi^{1/2}}{2\pi} \int_{0}^{\infty} \frac{\Gamma\left(\frac{1+\frac{s}{2}}{2}\right)\Gamma\left(\frac{1-\frac{s}{2}}{2}\right)}{\Gamma(1 - \frac{s}{2})} x^{-s}ds = \pi^{1/2} \int_{0}^{\infty} \frac{\tan\left(\frac{\pi}{2} s\right)\Gamma\left(\frac{s}{2}\right)}{\Gamma\left(\frac{1-s}{2}\right)} x^{-s}ds
\]

where one can take \( C \) also to be the critical line.

The corresponding duality relationships to the Zeta function are given by \((\text{[ETi]} \, 2.1, \text{[HEd]} \, 1.6ff)\):

i) \[
-\frac{\zeta(s)}{s} = \int_{0}^{\infty} \rho(t) \frac{1}{t^s} dt = \int_{0}^{\infty} x^s \rho(x) \frac{dx}{x} \quad \text{for } 0 < \Re(s) < 1
\]

ii) \[
\xi(s) := \zeta(s)\Omega(s) = \overline{\xi}(1 - s) \quad \text{for all complex } s \in C
\].
**Rational:** We refer to [HEd] 10.1, 10.3, 10.5, [ETI]2.11: The constant, non-vanishing Fourier terms of

$$
\rho(x) = \frac{1}{2} - \sum_{n=1}^{\infty} \sin\frac{2\pi nx}{2e^{\Pi}}, \quad \theta(x) = 1 + 2\sum_{n=1}^{\infty} f(nx)
$$

jeopardize the application of the Müntz formula to build the Riemann duality equation as transforms of a self-adjoint integral operator. The alternatively defined density function \( \widetilde{f}(x) := xf'(x) \) with its corresponding Mellin transform

$$
\Gamma(1+\frac{s}{2})\pi^{-s/2} = \int_{0}^{\infty} x^{s}(xf'(x)) \frac{dx}{x} = \int_{0}^{\infty} x^{s-1}df
$$

is the today’s basic “trick/idea” to overcome the conceptual problem of the non-vanishing Fourier term (just by differentiating). Its consequence of a reduced regularity of \( f' \) is balanced/leveraged by a corresponding multiplication with the factor \( x \) again. This then rebuilds the original structural properties of \( f \) (but just enabled by the special exponential function structure of \( f \), only). The (too high!) prize to be paid is the loss of the essential Theta function property. Our alternative solution concept is applying as alternative density function just the Hilbert transform of \( f \) (which doesn’t change the regularity (in a \( L_{\infty} \) – sense), keeps the Theta function property, while leading to a vanishing Fourier term at the same time), i.e. the alternative concept is about (in a distributional sense) a replacement of

$$
x^{s}(xf'(x)) \rightarrow f_{H}(x) := [H(f)](x) = 4\pi \int_{0}^{\infty} f(\xi) \sin(2\pi \xi x) d\xi,
$$

$$
\Omega(s) = (s-1)\int_{0}^{\infty} x^{s}(xf'(x)) \frac{dx}{x} \rightarrow \Omega_{H}(s) := \int_{0}^{\infty} x^{s}f_{H}(x) \frac{dx}{x} = \pi^{1-s/2} \tan(\frac{\pi}{2}s)\Gamma(\frac{s}{2}).
$$

**Remark:** Correspondingly with respect to the fractional part function we put

$$
\Omega_{\zeta}(s) := \sqrt{\frac{\pi}{2}} \frac{\Gamma(\frac{s}{2})}{\Gamma(\frac{1-s}{2})}.
$$

The (only) prize to be paid by our “distributional approach” is, that the corresponding Riemann duality relationship is “only” valid in a weak sense as the Hilbert transform creates \( L_{2} \) – function only, but at the same time it transforms \( L_{2} \) – function to \( L_{2} \) – function, i.e. it’s a isometry onto \( L_{2} \). For an analysis of periodic distributions (also in the context of the Poisson summation formula) and Fourier series we refer to [BPe] chapter 2, §11.

We note that the structure of \( \hat{f}_{H} \) corresponds to the structure of \( cxf'(ax) \) ([KBr3], appendix), i.e. it holds

$$
2\hat{f}_{H}(2\pi x) = -2i\int_{0}^{1} e^{-\frac{sx^{2}}{2}} \frac{dt}{\sqrt{t(1-t)}} = i\int_{0}^{1} \frac{dx}{\sqrt{t(1-t)}}\left[e^{-\frac{x^{2}}{2}}\right] \frac{dt}{\sqrt{t(1-t)}}.
$$
Two $H_{-1}, H_0$–related distributional Zeta functions
as transforms of self-adjoint integral operators

For $u, v \in L_2(0,2\pi)$ Hilbert space theory provides the properties (e.g. [BPe], [KBr1/2/3/4]):

$$Hu, Hv \in L_2(0,2\pi), \quad (Hu,v) = -(u,Hv), \quad (Hu)_{v=0} = (Hv)_{u=0} = 0$$

and

$$(u, \lambda) = (v, \lambda) \quad \text{for all} \quad \lambda \in H \quad \Leftrightarrow \quad (Hu, \mu) = (Hv, \mu) \quad \text{for all} \quad \lambda = H\mu \in H, \mu \in H.$$  

We apply the properties above to the two Theta function relationships based on the Gauss-Weierstrass function and the fractional part functions in corresponding Hilbert scale framework: Let $\omega_{ij}(x) := Hp(x) = -\log 2\sin(\pi x)$ resp. $\omega_{kj}(x) := Hg(x)$ denote the (periodical) Hilbert transforms of the fractional part function resp. of the Theta function. Let $\overline{g}$ be defined by

$$\overline{g}(x) := \frac{1}{x} g\left(\frac{1}{x}\right).$$

Then with respect to the inner products of the Hilbert spaces $H_{-1}, H_0$ the integral "density" functions $\omega_i(x)$ for $i = -1, 0$ fulfill (in the following weak sense) the Theta function property (remark (*), [BPe] examples 9.9-9.11, 9.13, 11.12, Corollary 11.9, §12, [KBr1], [KBr2]):

$$(\omega_i, \lambda)_i = (\overline{\omega_i}, \lambda)_i \quad \text{for all} \quad \lambda \in H_i.$$

The Theta function property is equivalent to a Riemann duality type equation for the corresponding Mellin transformed holomorphic functions $\zeta_i, s = \zeta_i(s)$ ([HHa]), if all integrals are convergent. This is ensured in the corresponding Hilbert space frameworks $H_{-1}, H_0$:

As a consequence in the critical stripe the “functions” $\zeta_i, s = \zeta_i(s)$ fulfill in a weak (distributional) $H_i$–sense following duality equations ([KBr3], see also [RDu])

$$D_{-1} : \quad \zeta_{-1}(s) \Omega_{-1}(s) = \int_0^\infty \omega_{-1}(t) y^s \frac{dt}{t} = \int_0^\infty x^{-s} \omega_{-1}(x) \frac{dx}{x} = \zeta_{-1}(1-s) \Omega_{-1}(s)$$

$$D_0 : \quad \zeta_0(s) \Omega_0(s) = \int_0^\infty \omega_0(1-t) y^s \frac{dt}{t} = \int_0^\infty x^{-s} \omega_0(x) \frac{dx}{x} = \zeta_0(1-s) \Omega_0(1-s).$$

At the same time the Hilbert space frameworks provide a self-adjoint integral function representation (with distributional Zeta function transforms defined within the critical stripe) along the “symmetry” line defined by the identity $s = 1 - s.$
This puts a new light also on the results and propositions of Ramanujan, which are qualified/“described" in a form like e.g.:

[CBe] 8, Entry17(iv): “Ramanujan informs us to note that ….. which also is devoid of meaning” .... “may be formally established by differentiating the well known equality” ....

As a consequence it holds:

**Proposition:** The complex functions $\zeta(s)$ defined by $D_1, D_0$ are identical to the Zeta function in a weak sense with respect to the norms of the Hilbert spaces $H_{-1}, H_0$. At the same time they are transforms of convolution integrals and “symmetric” with respect to $s = 1 - s$. Therefore all its zeros lie on the critical line.

*This proves the Riemann Hypothesis* as by definition the zeros of the Zeta function are (in a distributional sense) the same as those of $\zeta(s)$. Therefore, by density arguments it follows, that this is also valid in a strong sense.

**Remark:** The Hilbert spaces $H_{-1}, H_0$ above provide an alternative framework for current tauberian theory (see also [LGa]). In order to give obvious reasons for this we recall from [HPi], 1.1, 1.2, 2.1:

“*Tauberian theorems are concerned with relationships*

\[
(T_x)(u) := \int k(u,v)s(v)dv = g(u)
\]

*and ...(about) ... conclusions about the behavior of $s(v)$ derived from assumptions about $g(x)$. “.. they” are generally much deeper than corresponding abelian theorem. Tauberian theorems are mainly concerned with convergence or other order properties of $s(x)$ and $g(x)$ as $x \to \infty”. .... The role of the tauberian condition in the tauberian theorem is shown clearly in the proof of the following simple theorem.*

**THEOREM 1.** Suppose that $k(x) \in L_{(-\infty,0)}$, $\int k(x)dx = 1$, $s(x) = o(1)$ and that, if $\varepsilon > 0$, we define $\delta = \delta(\varepsilon, x)$, so that

\[
\lim_{x \to \infty} \delta(\varepsilon, x) = \infty \quad \text{and} \quad |s(y) - s(x)| < \varepsilon \quad \text{for} \quad |y - x| < \delta .
\]

Then

\[
(T_x)(x) = g(x) \to \infty \quad \text{for} \quad x \to \infty \quad \text{implies that} \quad s(x) \to \infty \quad \text{for} \quad x \to \infty .
\]
Appendix

**Lemma:** The Mellin transform of \( f_H(x) \) is given by

\[
M[f_H(s)] = 2\pi^{s/2} \Gamma\left(\frac{1+s}{2}\right) \int_0^\infty \frac{1}{x^{s/2}} \cos x^2 \cos s x^2 dx = \pi^{(1-s)/2} \tan(\frac{\pi}{2} s) \Gamma\left(\frac{s}{2}\right),
\]

for \( \text{Re}(1-s) > 0 \)

with

\[
\int_0^\infty \frac{1}{x^{s/2}} \cos x^2 dx = \sqrt{\pi} \frac{\Gamma\left(\frac{1-s}{2}\right)}{\Gamma\left(\frac{1}{2}-\frac{s}{2}\right)}
\]

and

\[
\frac{\Gamma\left(\frac{1+s}{2}\right) \Gamma\left(\frac{1-s}{2}\right)}{\Gamma\left(\frac{1}{2}\right)} = \frac{\pi \sin(\frac{\pi}{2} s)}{\pi \cos(\frac{\pi}{2} s)} = \tan(\frac{\pi}{2} s) \Gamma\left(\frac{1}{2}-\frac{s}{2}\right) = \cot(\frac{\pi}{2} (1-s)) \Gamma\left(\frac{1}{2}\right).
\]

**Proof:** It follows by the substitution of variables by \( \pi x^2 (1-t) = y \), \( t = z^2 \) and \( z = \sin \tau \)

\[
\int_0^\infty x^s f_H(x) \frac{dx}{x} = 2\sqrt{\pi} \int_0^\infty x^{s/2} e^{-\pi y/2(1-t)} \frac{dx}{x} = 2\sqrt{\pi} \int_0^\infty \frac{1}{x^{s/2}} \cos x^2 \cos s x^2 dx
\]

\[
= 2\sqrt{\pi} \int_0^\infty \frac{1}{x^{s/2}} \cos x^2 \cos s x^2 dx = \pi^{s/2} \Gamma\left(\frac{1+s}{2}\right) \int_0^\infty \frac{1}{x^{s/2}} \cos x^2 \cos s x^2 dx
\]

and therefore

\[
\pi^{s/2} \Gamma\left(\frac{1+s}{2}\right) \int_0^\infty \frac{1}{x^{s/2}} \cos x^2 \cos s x^2 dx = \pi^{s/2} \Gamma\left(\frac{1+s}{2}\right) \int_0^\infty \frac{1}{x^{s/2}} \cos x^2 \cos s x^2 dx
\]

\[
= \pi^{s/2} \Gamma\left(\frac{1+s}{2}\right) \int_0^\infty \frac{1}{x^{s/2}} \cos x^2 \cos s x^2 dx
\]

From [SGr] 3.621 we get

\[
\int_0^{\pi/2} \sin^{-1} x \cos^{-1} x dx = \frac{1}{2} B(\mu, \nu), \quad \text{Re}(\mu), \text{Re}(\nu) > 0.
\]

**Corollary:** It holds

\[
\frac{1}{2\pi} \int_0^\infty f_H(x) \frac{dx}{x} = \frac{\pi}{2} \cos \left(\frac{\pi}{2} x\right) \quad \text{resp.} \quad \tan(\frac{\pi}{2} x) = \frac{\cos(\frac{\pi}{2} x)}{\sin(\frac{\pi}{2} x)} = \frac{\tan(\frac{\pi}{2} x)}{\frac{\pi}{2}} \rightarrow \pi.
\]

**Proof:** It follows with \( s \rightarrow 0 \) and the following formulas ([SGr] 0.234, 1.421, 8.322):

\[
\sum_{k=0}^{n-1} \frac{1}{(2k+1)^{n}} = \frac{\pi^{2}}{8}, \quad \text{tan}(\frac{\pi}{2} x) = \frac{4}{\pi} \sum_{k=0}^{n} \frac{1}{(2k+1)^{n}}
\]

\[
\Gamma(\frac{3}{2}) = \frac{2}{\sqrt{\pi}} \Gamma(\frac{1}{2}) = \frac{2}{\sqrt{\pi}}
\]

\[
\frac{\pi}{2} \int_0^{\pi/2} B(\mu, \nu) \frac{dy}{y} = \int_0^{\pi/2} \cos \left(\frac{\pi}{2} x\right) \frac{dy}{y} = \frac{\pi}{2} \int_0^{\pi/2} \cos \left(\frac{\pi}{2} x\right) \frac{dy}{y}
\]

**Remark:** In the \( H^- \) sense it holds for \( 0 < \text{Re}(s) < 1 \)

\[
\int_0^\pi x^s \rho_H(x) \frac{dx}{x} = \frac{\pi}{2} \int_0^{\pi/2} \frac{dy}{y} \int_0^\infty \cos(y) \cos(x^2) \cos(y) \frac{dy}{y} = \frac{\pi}{2} \int_0^{\pi/2} \cos(y) \cos(y) \frac{dy}{y} = \frac{\pi}{2} \int_0^{\pi/2} \cos(y) \cos(y)
\]

and therefore

\[
\int_0^{\pi} x^s \rho_H(x) \frac{dx}{x} = \frac{\pi}{2} \int_0^{\pi/2} \frac{dy}{y} \frac{dy}{y} = \frac{\pi}{2} \int_0^{\pi/2} \frac{dy}{y}
\]
Remark: From [SGr] 3.952 we recall

\[
f_{n}(x) = 4\pi \int_{0}^{1} f(\xi) \sin(2\pi \xi x) d\xi = 4\pi f(x) F_{\beta}(\frac{1}{2} \cdot \alpha, \alpha) ,
\]

\[
f_{n}(x) = 2\sqrt{\pi} f(x) \int_{0}^{1} e^{\pi^{2} t} t^{-1/2} dt = -\frac{1}{2\pi} \int_{0}^{1} t^{-1/2} \frac{d}{dx} \left[ e^{-\pi^{2} (n+1)t} \right] \frac{dt}{1-t}
\]

whereby

\[
F(\alpha; \beta; z) = \sum_{n=0}^{\infty} \frac{(-\alpha)^{n}}{n!} \sum_{n=0}^{\infty} \frac{(-\beta)^{n}}{n!} = \frac{\Gamma(\beta)}{\Gamma(\beta - \alpha) \Gamma(\alpha)} \int_{0}^{1} e^{\pi^{2} t} (1-t)^{-\alpha-1} dt ,
\]

\[
(\alpha)_{n} = \alpha(\alpha + 1) \ldots (\alpha + n - 1); (\alpha)_{0} := 1
\]
denote the confluent hyper-geometric function (series) (see also [NNi] §65).

Lemma: The Fourier transform of the odd function

\[
f_{n}(x) = -\frac{1}{2\pi} \int_{0}^{1} t^{-1/2} \frac{d}{dx} \left[ e^{-\pi^{2} (n+1)t} \right] \frac{dt}{1-t}
\]

is given by

\[
\hat{f}_{n}(x) = -\frac{i}{2\pi} \int_{0}^{1} t^{-1/2} \frac{x}{\sqrt{1-t}} e^{-\pi^{2} t} \frac{dt}{1-t} = -i \frac{x^{3/2}}{\sqrt{\pi}} \frac{d}{dy} \frac{e^{-\frac{y^{2}}{4(1-t)}}}{\cos^{2} y}
\]

resp.

\[
-\hat{f}_{n}(x) = 2i \int_{0}^{1} \frac{\sqrt{1-t}}{4\pi} e^{-\frac{x^{2}}{4(1-t)}} \frac{dt}{h(1-t)} \quad \text{with} \quad h(t) := \sqrt{1-t} .
\]

Proof: As \( f_{n}(x) \) is odd, one gets

\[
\hat{f}_{n}(\xi) = F\{f_{n}(\xi)\} = \frac{2i}{\sqrt{2\pi}} \int_{0}^{1} f_{n}(x) \sin(x\xi) dx .
\]

We recall the property

\[
F\{g'(\xi)\} = i\xi F\{g(\xi)\} .
\]

Hence it holds

\[
F\left[ \frac{d}{dx} \left[ e^{-\pi^{2} (n+1)t} \right] \right] = i\xi F\left\{ e^{-\pi^{2} (n+1)t} \right\} = \frac{i\xi x^{3}}{\sqrt{1-t}} e^{-\frac{x^{2}}{4(1-t)}}
\]

and therefore

\[
\hat{f}_{n}(x) = \frac{i}{2\pi} \int_{0}^{1} t^{-1/2} \frac{x}{\sqrt{1-t}} e^{-\frac{x^{2}}{4(1-t)}} \frac{dt}{1-t} = \frac{i}{2\pi} \int_{0}^{1} \frac{x}{\sqrt{\pi(1-\tau)}} e^{-\frac{x^{2}}{\pi(1-\tau)}} \frac{d\tau}{\tau} .
\]
Known criteria

There is a “modified” Zeta function representation

\[ \xi^*(s) := \zeta(s)\Gamma^*(s), \]

which can be realized

either

i) as a “convolution”

\[ \xi^*(1/2 + it) = (G \ast dF)(t) = \int_{-\infty}^{\infty} G(z-it)dF(u) \]

or

ii) as “Fourier integral”

\[ \xi^*(z) = \int_{0}^{\infty} u^{-z} F(u) \phi(\log u) \frac{du}{u} \]

where

\[ g(z) := \int_{0}^{\infty} u^{-z} F(u) \frac{du}{u} \]

has all its zeros on the critical line.
Holomorphic function in the distributional sense

**Definition (HF), [BPe] §15, 16, Distribution valued and boundary values of holomorphic functions:**

Let \( z \to g_z \) be a function defined on an open subset \( U \subset \mathbb{C} \) with values in the distribution space. Then \( g_z \) is called a holomorphic in \( U \subset \mathbb{C} \) (or \( g(z) := g_z \) is called holomorphic in \( U \subset \mathbb{C} \) in the distribution sense, if for each \( \varphi \in C^\infty_c \) the function \( z \to (g_z \cdot \varphi) \) is holomorphic in \( U \subset \mathbb{C} \) in the usual sense.

**Remark: ([BPe])** In the one-dimensional case any complex-analytical function, as any distribution \( f \) on \( \mathbb{R} \), can be realized as the “jump” across the real axis of the corresponding in \( \mathbb{C} - \mathbb{R} \) holomorphic Cauchy integral function

\[
F(x) := \frac{1}{2\pi} \int \frac{f(t)dt}{t-x},
\]

given by

\[
(f, \varphi) = \lim_{\varepsilon \to 0} \int F(x+iy) - F(x-iy))\varphi(x)dx.
\]

In the one-dimension case the Riesz operator is identical with Hilbert transform ([BPe] 2.9), that is a Cauchy principle-valued function, expressed in the form

\[
(Ru)(x) := (Hu)(x) := \lim_{\varepsilon \to 0} \int \frac{u(y)}{\pi} \frac{dy}{x-y} = \frac{1}{\pi} \int \frac{u(y)}{x-y} dy
\]

for \( x \to 0 \),

whereby the Fourier coefficients are given by

\[
(Hu)_\nu = -i \text{sgn}(\nu) u_\nu,
\]

i.e. the Hilbert transform is a classical pseudo-differential operator ([BPe] 3.6) with symbol \( i \text{sgn}(s) \).

The principle value \( P.V.\{1/x\} \) of the not locally integrable function \( 1/x \) is the distribution \( g \) defined by ([BPe] 1.7)

\[
(g, \varphi) := \lim_{\varepsilon \to 0} \int \varphi(x) \frac{dx}{x} = \int \log|x|\varphi'(x)dx
\]

for each \( \varphi \in C^\infty_c \).

The relationship of this specific principle value to the Fourier and Hilbert transforms is given by ([BPe] 2.9)

\[
\left[ P.V.\left\{\frac{1}{x}\right\}\right] = -i\pi \text{sgn}(s) \quad \text{and} \quad \left[ P.V.\left\{\frac{1}{x}\right\}\right] = -2\pi P.V.\left\{\frac{1}{x}\right\}.
\]

The Hilbert transform of the function \( \sin(\alpha t) \) is given by \( \cos(\alpha t) \). This gives a \( \pm \frac{\pi}{2} \) phase-shift operator, which is another basic property of the Hilbert transform. It can be used to remove the not needed negative frequency axis.

12
There is an obvious relationship between the Mellin and the Laplace transform:

\[ F(s) = \int_0^\infty f(t)t^{s-1} \, dt = \int_0^\infty f(e^{s} - x)e^{-sx} \, dx = \frac{1}{s} \int f\left(1 - \frac{1}{y}\right)^{s-1} \, \frac{dy}{y}. \]

If \( f \in L^1(\mathbb{R}^n) \) has compact support the Laplace transform of \( f \) is the entire function \( F \) defined by ([BPe] §12)

\[ F(s) = \int e^{-\langle s,x \rangle} f(x) \, dx = f(\eta - i\xi). \]

This definition extends immediately to distributions with compact support. If \( f \in E'(\mathbb{R}^n) \) we define the Laplace transform \( F \) of \( f \) by

\[ F(s) = \left\{ f, e^{-\langle s,x \rangle} \right\}. \]

In the context of characterizations of differentiability we recall from [EST] VIII, §5:

**Theorem 6 (Zygmund condition):** Suppose \( f \in L_2(\mathbb{R}^n) \). Then for almost every \( x_0 \in \mathbb{R}^n \) the following two conditions are equivalent:

i) \( f \) has a derivative in the \( L_2 \) sense at \( x_0 \in \mathbb{R}^n \)

ii) \[ \int_{\mathbb{R}^n} \frac{|f(x_0 + \xi) + f(x_0 - \xi) - 2f(x_0)|^2 \, d\xi}{|\xi|^{n+2}} < \infty. \]
